Technology and Protest: Online Appendix

Zuheir Desai*

Alexander Lee[†]

August 8, 2019

The online Appendix is organized as follows. We first present analyses of additional hypotheses developed in the main paper. Section A.1 and Section A.2 discuss whether EVMs had an effect on the number of valid votes and whether EVMs increased fragmentation in a constituency. We then address the question on turnout in Section A.3. We also address the impact of electronic voting machines on fraud in Section A.4. Finally, we report tables including results about control variables from the main text in Section A.5.1, and all other tables are reported in Section A.5.2.

A.1 Effects on Valid Voting

The claim that the fall in invalid voting is normatively important hinges on the assumption that the voters who previously cast invalid votes now cast valid votes. If voters who previously cast invalid votes simply stopped turning out after the introduction of EVMs, the reform would have

no political effect, and only a very doubtful normative value. This concern is especially valid

because it appears that turnout may decrease with the introduction of EVMs (see Section A.3).

However, the results seem to suggest that EVMs had a net positive effect in terms of "enfran-

chisement," with the decline in invalid votes swamping the poorly estimated decline in turnout.

1

These results are presented in Table A.6, which shows the results of a difference-in-differences model with the number of valid votes cast in a constituency as a dependent variable. The coefficient on EVMs is positive in all models, although it is not always significant. Thus, we can reasonably conclude that EVMs have an overall non-negative effect on enfranchisement of Indian citizens since they resulted in a smaller number of votes being disregarded as invalid.

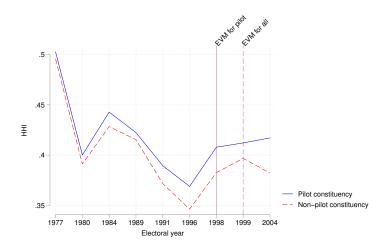

Note that this estimated effect may represent an underestimate of the enfranchising effects of EVMs. To the extent that EVMs successfully prevent ballot box stuffing (their primary intended purpose), they should lead to a reduction in the number of legally valid but fraudulent votes, which would lead to EVM introduction having a spurious "disenfranchising" effect. The fact that the number of valid votes increases regardless is strong evidence that EVM introduction led many voters who would previously have cast invalid votes to cast valid ones.

A.2 Fragmentation

The Herfindahl-Hirschman Index (HHI) is the sum of the squared vote shares of all candidates in a constituency. It is an indicator of the relative fractionalization in the electoral district. Thus, in the case of a small number of parties dominating the election, the HHI is close to 1, and if there are many parties with similar vote shares, then it is close to 0. As before, we first present evidence on the pre-trends of HHI in Figure A.1. The trends seem to move together, with the relatively urban and richer pilot constituencies showing more concentration of vote shares and the non-pilot, rural constituencies being more competitive (in terms of the fragmentation of the vote). The trends are relatively parallel for pilot and non-pilot constituencies, and the effect of lags and leads of the treatment is statistically insignificant (Table A.14).

Table A.11 shows the effect of electronic voting machines (EVMs) on the HHI. EVMs have a negative effect on HHI in all models considered. The smaller the HHI, the more the fragmentation within the electoral district (as votes are divided among more candidates). Thus, a negative

Figure A.1: Pre-trends for HHI

Notes. The blue solid line plots the average HHI in all pilot constituency across election years while the red dashed line plots the average HHI in non-pilot constituencies. The year 1998 marks the last election before the introduction of EVMs. Thus, 1999 is the first post-treatment year for the pilot constituencies. In the year 2004, the non-pilot constituencies also used EVMs.

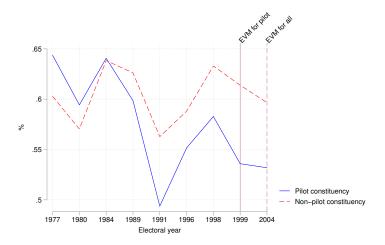

coefficient indicates that EVMs increase fractionalization. However, the coefficient in Column (2), the standard difference-in-differences model, is not significant. This is because HHI is affected by other time varying variables such as the number of candidates in the district. After having controlled for these variables, Columns (3) and (4) indicate that EVMs had a significant negative effect on the HHI. This effect is robust to phase-year controls.

A.3 Turnout

Do voters who previously cast invalid ballots still turn out? In the Indian case, since EVMs make it impossible to cast an invalid ballot, voters who intentionally casted spoiled ballots could now loose their incentive to go to the polls. As before, we examine the pre-trends of the early treatment pilot constituencies and the non-pilot constituencies. Compared to the pre-trends of invalid vote rates, the pre-trends for turnout do not show evidence of parallel trends.

In particular, figure A.2 shows that there was a perceptible negative trend in turnout in the

Figure A.2: Pre-trends for turnout

Note: The blue solid line plots the average turnout rate in all pilot constituency across election years while the red dashed line plots the average turnout vote rate in non-pilot constituencies. The year 1998 marks the last election before the introduction of EVMs. Thus, 1999 is the first post-treatment year for the pilot constituencies. In the year 2004, the non-pilot constituencies also used EVMs.

treatment districts relative to the control districts in the early 1990s, though the gap did not appear to be increasing in the two elections before 1999. This trend may reflect the growing turnout gap in India between poor and rich voters, with rich voters tending to be less involved (Ahuja and Chhibber, 2012). The second column in Table A.21 conducts a placebo analysis by comparing the effects of the EVM treatment on turnout in the year 1999 versus other electoral years. According to the results, while the pilot constituencies have consistently smaller turnout rates compared to the non-pilot constituencies across all electoral years, the difference in the treatment year is larger than any other year.

Table A.12 examines the effect of EVM introduction on voter turnout. The results suggest that EVMs have a slight negative effect on turnout. Substantively, the effect is a little over two percentage points, a little smaller than the overall observed decline in turnout during this period, from 62.5% in 1998 to 59% in 2004.

¹The perceptible drop in turnout in pilot constituencies in 1991 could be because of the assassination of Rajiv Gandhi midway through the elections.

However, we are cautious about whether EVMs affect turnout. Firstly, the pre-trends seem to suggest that the parallel trends assumption is not valid in the case of turnout. Secondly, an analysis of lags and leads of treatment in Table A.21 shows that the pilot constituencies consistently were different from non-pilot constituencies in terms of turnout. Third, these results are not robust to clustering standard errors at the state level, or the state-year level. Thus, it seems likely that turnout rates within each state-year dyad are not independent. And, finally, Panel (c) of Table A.13 in particular shows that voting machines have no effect on turnout when the analysis is restricted to the geographically proximate constituency subsample and the matched constituency subsample.

A.4 EVMs and Fraud

A.4.1 Partisan Effects

If EVMs were in fact altering the chances of successful electoral fraud, we should expect their introduction to increase the vote for specific parties or types of parties, especially those likely to be able to fraudulently manipulate the machines. Note that while study of whether different voting technologies favor or disfavor particular political parties has been the topic of discussion in the literature, there is little proof of systematic effects (as opposed to analyses of particular races) (Stewart, 2011).

We do not find any systematic effects on the vote shares of specific political parties, such as the INC or the BJP, or on the vote shares of electoral alliances such as the BJP-led National Democratic Alliance (NDA), the INC-led United Progressive Alliance (UPA),² or the Third Front. These results are not reported for reasons of space, but are available on request from the authors.

Table A.18 analyzes the effect of EVMs on the vote share of the incumbent party of the state

²While the UPA was formally created after the 2004 election, the INC was allied with several regional parties during the 1998 and 1999 elections. We also examined whether EVMs had any effect on the vote shares of the INC+allies, and found no systematic effects.

government. In the Indian context, the state government is the agency with effective control over the police and the district administration, which they might use for electoral advantage. Despite the ECI's careful attempts to limit such influence, the state incumbents clearly have a much greater opportunity to engage in fraud than any other party, and a decline of the vote for this party in areas with EVMs would be strong evidence for fraud. Conversely, if EVMs had a positive effect on state incumbent vote share, we might suspect the sort of systematic machine tampering feared by Kumar and Walia (2011).

However, Table A.18 shows that there is little evidence for such an effect. EVMs have a small positive relationship with state incumbent vote share, but this effect is statistically insignificant at conventional levels. State incumbents thus appear not to be affected by the introduction of EVMs, either because of the quality of the ECI's precautions or because EVMs in ineffective in preventing the types of fraud they use.

A.4.2 Voter Verification

One of the defining features of "direct recording" EVMs is that votes are recorded on the memory unit of the machine, rather than on paper. This makes it impossible for voters to directly verify that their vote has been cast in the way that they wish, and theoretically possible to alter vote totals within the machine in ways that would be difficult to detect. The most commonly recommended solution to this problem is a voter-verified paper audit trail (VVPAT) (Kohno et al., 2004). VVPAT machines differ from other EVMs in that the voter receives a paper "receipt" for her vote, which can then be compared to the machine-reported totals in a post-election audit.

In 2013, the Indian supreme court ordered the election commission to introduce VVPAT technology in all elections. In the 2014 national election, eight constituencies had VVPAT. This makes possible a difference-in-differences analysis similar to that in Section A.4.1, using two years (2009 and 2014). Since the announced goal of VVPAT is the reduction in fraud, we will focus on the

results for two outcomes that might plausibly be correlated with fraud: The level of voting for the state incumbent party and the turnout rate.³

Tables A.19 and A.20 show the results of this analysis. Relative to ordinary machines, the introduction of VVPAT machines appears to have no negative effect on turnout or vote for incumbents: If anything, turnout appears to increase very slightly in treated constituencies. The fact that the effect of VVPAT machines is indistinguishable from that of non-auditable eletronic voting machines does not mean that these innovations are useless, since this technology may possibly prevent election fraud in the future. It does, however, indicate that these machines are not associated with changes in political outcomes relative to 2004 and 2009, either because no large-scale fraud occurred during this period or because VVPAT has not decreased the types of fraud that did take place.

A.4.3 Turnout and Fraud

It is possible that the effect of EVMs can be found not in the vote totals but in the turnout figures. We especially focus on regional variation in the turnout effect, given that we expect to see decreases in turnout in constituencies that are more prone to booth-capturing. If booth capturing was common before 1999, some portion of the turnout recorded by the ECI represents fraudulent votes, entered into the voter register and ballot box by armed goons. If the introduction of EVMs reduced the incidence of booth capture (as it was designed to do), we should expect turnout to decline with their introduction in areas where this practice was common.

Interestingly, the effect of EVMs on turnout is not larger in areas that would intuitively be identified as more corrupt. One commonly used measure of corruption in Indian public life is the tendency of many candidates to face serious criminal charges (Vaishnav, 2017; Aidt, Golden and Tiwari, 2011). Using Aidt, Golden and Tiwari's (2011) data on the criminal status of candidates in the 2004 and 2009 elections, we define a constituency as "criminal" if there was at least one

³Results showing VVPAT has no association with invalid voting are not reported for reasons of space.

criminal who ran for election. Table A.14 results show that there is no estimated effect of EVMs on turnout in these constituencies. Similar results (not reported for reasons of space) could be obtained by interacting EVM introduction with state-level poverty, insurgency, or location in the Hindi belt.

These weak results are consistent with design of the machines, since EVMs do not make it impossible for political parties to capture polling booths, but only increase the time it takes to do so. While it is still possible to take control of polling booths, the delay built into the machines means control must be maintained for a longer time if all the booth's ballots are to be casted. Anecdotal evidence suggests that political parties still indulge in fraudulent voting, even with the presence of EVMs (Rohde, 2004).

Standard errors in parentheses

Notes. This table shows the impact of EVMs on invalid vote rates in Lok Sabha electoral constituencies. Column (1) runs a simple OLS model, Column (2) reports the results of a basic diff-in-diff regression with constituency specific fixed effects and electoral year fixed effects, Column (3) includes time-varying control variables such as the INC vote share, BJP vote share, number of candidates in the constituency, the eventual margin of victory, and turnout rate, Column (4) replaces electoral year fixed effects by phase-year fixed effects. Finally, Column (5) conducts a basic diff-in-diff regression with constituency and year fixed effects on constituencies with more than 40% of its population living in urban areas. Standard errors have been clustered by constituency for all models.

Standard errors in parentheses

Notes. This table shows the impact of EVMs on the HHI in Lok Sabha electoral constituencies. Column (1) runs a simple OLS model, Column (2) reports the results of a basic diff-in-diff regression with constituency specific fixed effects and electoral year fixed effects, Column (3) includes time-varying control variables such as the INC vote share, BJP vote share, number of candidates in the constituency, the eventual margin of victory and turnout rate, Column (4) replaces electoral year fixed effects by phase-year fixed effects. Finally, Column (5) conducts a basic diff-in-diff regression with constituency and year fixed effects on constituencies with more than 40% of its population living in urban areas. Standard errors have been clustered by constituency for all models.

Notes. This table assigns placebo treatments to pilot constituencies in electoral years prior to 1999. Column (1) investigates the effect of placebo EVM treatment on invalid vote rates, Column (2) looks at the HHI, Column (3) does the same for turnout rates, and Columns (4)-(7) look at the leads of treatment for the different measures of minor party vote share. The actual treatment year for pilot constituencies is 1999, and is marked by the bold and italic row. All errors have been clustered at the constituency level.

⁺ *p* < 0.10, * *p* < 0.05, ** *p* < 0.01, *** *p* < 0.001

Figure A.3: Pre-trends for other variables

Notes. The blue solid line plots the average values of the different variables in all pilot constituency across election years while the red dashed line plots the average of the control variables in non-pilot constituencies. The year 1998 marks the last election before the introduction of EVMs. Thus, 1999 is the first post-treatment year for the pilot constituencies. In the year 2004, the non-pilot constituencies also used EVMs.
